Precision tests of discrete symmetries in decays of positronium with the J-PET detector

Thursday, 14 July 2022 09:35 (20 minutes)

The Jagiellonian PET (J-PET) detector is the only device which enables estimation of positronium spin axis together with determination of polarization of photons from positronium annihilation on the event-by-event basis. This allows to test angular correlations in the annihilations of the lightest leptonic bound system and explore a new class of discrete symmetry odd operators that were not investigated before. Such measurement is equivalent to a search for possible violation of combined charge, parity, and time-reversal symmetries as yet another approach for a test of New Physics. Positronium, a bound state of electron and positron, as the lightest matter-antimatter system and at the same time an eigenstate of the C and P operators is an unique probe in such endeavor. With first measurements demonstrating such capabilities we are able to reach the precision of CPT and CP tests at permill level. In the talk we will describe experimental techniques and recent results of discrete symmetries tests in the decays of positronium in a whole available phase-space.

Presenter: Dr CZERWIŃSKI; JAGIELLONIAN UNVERSITY, POLAND, Eryk

Session Classification: Session 1
